DP-MAC: The Differentially Private Method of Auxiliary Coordinates for Deep Learning

Frederik Harder\textsuperscript{1} Jonas Köhler\textsuperscript{2} Max Welling\textsuperscript{3} Mijung Park\textsuperscript{4}

Abstract

Developing a differentially private deep learning algorithm is challenging, due to the difficulty in analyzing the sensitivity of objective functions that are typically used to train deep neural networks. Many existing methods resort to the stochastic gradient descent algorithm and apply a pre-defined sensitivity to the gradients for privatizing weights. However, their slow convergence typically yields a high cumulative privacy loss. Here, we take a different route by employing the method of auxiliary coordinates, which allows us to independently update the weights per layer by optimizing a per-layer objective function. This objective function can be well approximated by a low-order Taylor's expansion, in which sensitivity analysis becomes tractable. We perturb the coefficients of the expansion for privacy, which we optimize using more advanced optimization routines than SGD for faster convergence. We empirically show that our algorithm provides a decent trained model quality under a modest privacy budget.

1 Introduction

While providing outstanding performance, it has been shown that trained deep neural networks (DNNs) can expose sensitive information from the dataset they were trained on\cite{1, 2, 3, 4}. In order to protect potentially sensitive training data, many existing methods adopt the notion of privacy, called differential privacy (DP)\cite{5}. Differentially private algorithms often comprise of a noise injection step (e.g. during the training process), which is generally detrimental to performance and leads to a trade-off between privacy and utility. The amount of noise necessary for a desired level of privacy depends on the sensitivity of an algorithm, a maximum difference in its output depending on whether or not a single individual participates in the data. In DNNs, the sensitivity of an objective function is often intractable to quantify, since data appears in the function in a nested and complex way. In addition, such models have thousands to millions of parameters, one needs to safeguard, and require many passes over the dataset in training. As a result, providing meaningful privacy guarantees while maintaining reasonable performance remains a challenging task for DNNs.

One existing approach to this problem, DP-SGD\cite{6, 7, 8}, avoids complicated sensitivities, by applying a pre-defined sensitivity to the gradients, which are then perturbed with Gaussian noise before updating the weights to ensure DP. This work also introduces the moments accountant (MA)\cite{6}, a useful method for computing cumulative privacy loss when training for many epochs (a formal introduction to this method is found in Appendix A). In another line of recent work\cite{9, 10, 11}, DP training is achieved by approximating the nested objective function through Taylor approximation and perturbing each of the coefficients of the approximated loss before training.

In this paper, we combine the benefits of these two approaches. We modify the algorithm called the method of auxiliary coordinates (MAC), which allows independent weight updates per layer, by

\textsuperscript{1,2,4}: Max Planck Institute for Intelligent Systems, \textsuperscript{3}: University of Amsterdam
framing the interaction between layers as a local communication problem via introducing auxiliary coordinates [12]. This allows us to split the nested objective function into per-layer objective functions, which can be approximated by low-order Taylor’s expansions. In this case the sensitivity analysis of the coefficients becomes tractable.

2 DP-MAC

2.1 The Method of Auxiliary Coordinates

Here we provide a short introduction on the MAC algorithm (see [12] for details). Under a fully connected neural net with $K$ hidden layers, a typical mean squared error (MSE) objective is given by

$$E(W) = \frac{1}{2N} \sum_{n=1}^{N} ||y_n - f(x_n; W)||^2,$$

(1)

where $f(x_n; W) = f_{K+1}(\ldots f_2(f_1(x_n; W_1) \ldots; W_K)$. We denote $W$ as a collection of weight matrices of $(K + 1)$-layers, i.e., $W = \{W_k\}_{k=1}^{K+1}$, where the size of each weight matrix is given by $W_k \in \mathbb{R}^{D^k_{in} \times D^k_{out}}$.

Each layer activation function is given by $f_k(x_n; W_k) = f_k(W_k \top x_n)$, and $f_k$ could be any type of element-wise activation functions. In the MAC framework [12], the objective function in eq. 1 is expanded by adding auxiliary variables $\{z_{kh}\}$ (one per datapoint) such that the optimization over many variables are decoupled:

$$E(W, Z; \mu) = E_o(W, Z) + \sum_{k=1}^{K} E_k(W, Z, \mu),$$

(2)

where the partial objective functions at the output layer and at the $k$-th layer are given by $E_o(W_{K+1}, Z_K) = \frac{1}{2N} \sum_{n=1}^{N} ||y_n - f_{K+1}(z_{K,n}; W_{K+1})||^2$, and $E_k(W_k, Z_k, Z_{k-1}, \mu) = \frac{1}{2N} \sum_{n=1}^{N} ||z_{kh,n} - f_k(z_{k-1,n}; W_k)||^2$. Alternating optimization of this objective function w.r.t. $W$ and $Z$ minimizes the objective function. In this paper, we set $\mu = 1$, as suggested in [12]. For obtaining differentially private estimates of $W$, it turns out we need to privatize the $W$ update steps only, while we can keep the $Z$ update steps non-private, as has been studied in Expectation Maximization (EM) type algorithms before [13, 14].

To make this process DP, we first approximate each objective function as 1st or 2nd-order polynomials in the weights. Then, we perturb each approximate objective function by adding noise to the coefficients and optimize it for estimating $W$. How much noise we need to add to these coefficients depends on the sensitivity of these coefficients as well as the privacy loss we allow in each training step. The final estimate $W_T$ depends on estimates $W_t$ and $Z_t$ for all $t < T$ and so we keep the privacy loss per iteration fixed and compute the cumulative loss using the moments accountant.

2.2 DP-approximate to the per-layer objective function

First, we consider approximating the per-layer objective function via the 2nd-order Taylor expansion

$$E_k(W_k) = \frac{1}{2N} \sum_{n=1}^{N} ||z_{kh,n} - f_k(z_{k-1,n}; W_k)||^2 \approx a_k + \sum_{h=1}^{D^k_{out}} w_{kh} \top b_{kh} + \sum_{h=1}^{D^k_{out}} w_{kh} \top C_{kh} w_{kh},$$

where $w_{kh} \in \mathbb{R}^{D^k_{in}}$ is the $h$-th column of the matrix $W_k$, and the derivation of each term $a_k, b_{kh} \in \mathbb{R}^{D^k_{in}}$, $C_{kh} \in \mathbb{R}^{D^k_{out} \times D^k_{out}}$ is given below. Here we choose to use the softplus function as an example activation function for $f$, but any twice differentiable function is valid. We introduce a new notation $T_n(w_{kh})$

$$E_k(W_k) = \frac{1}{2N} \sum_{n=1}^{N} \sum_{h=1}^{D^k_{out}} T_n(w_{kh})$$

(3)

where $T_n(w_{kh}) = z_{kh,n}^2 - 2z_{kh,n} f(w_{kh} \top z_{k-1,n}) + \{f(w_{kh} \top z_{k-1,n})\}^2$. We then approximate $T_n(w_{kh})$ by the 2nd-order Taylor expansion evaluated at $w_{kh}$. In the first optimization step, we approximate the loss function by the 2nd-order Taylor expansion evaluated at a randomly drawn $w_{kh} \sim \mathcal{N}(0, I)$. In the consecutive optimization step, we evaluate the loss function at the noised-up estimate $w_{kh}$ obtained from the previous optimization step.

$$T_n(w_{kh}) \approx T_n(\tilde{w}_{kh}) + (w_{kh} - \tilde{w}_{kh}) \top \partial T_n(\tilde{w}_{kh}) + \frac{1}{2} (w_{kh} - \tilde{w}_{kh}) \top \partial^2 T_n(\tilde{w}_{kh})(w_{kh} - \tilde{w}_{kh}),$$

(4)

where the derivative expressions of $T_n(w_{kh})$ are given by

$$\partial T_n(\tilde{w}_{kh}) = [-2z_{kh,n} f'(w_{kh} \top z_{k-1,n}) + 2f(w_{kh} \top z_{k-1,n}) f'(w_{kh} \top z_{k-1,n})] z_{k-1,n},$$

$$\partial^2 T_n(\tilde{w}_{kh}) = [-2z_{kh,n} f''(w_{kh} \top z_{k-1,n}) + 2f(w_{kh} \top z_{k-1,n}) f'''(w_{kh} \top z_{k-1,n}) + 2\{f'(w_{kh} \top z_{k-1,n})\}^2] z_{k-1,n} z_{k-1,n} \top.$$
From this, we define the coefficients \( a_k, b_k, C_k \) as:

\[
\hat{a}_k = \frac{1}{N} \sum_{n=1}^{N} \sum_{h=1}^{D_k} \left[ T_n(\hat{w}_{kh}) - \hat{w}_{kh}^\top \partial T_n^{kh} + \frac{1}{2} \hat{w}_{kh}^\top \partial^2 T_n^{kh} \right], \quad \hat{b}_k = \frac{1}{N} \sum_{n=1}^{N} \frac{D_k}{2} T_n^{kh}, \quad \hat{C}_k = \frac{1}{N} \sum_{n=1}^{N} \frac{D_k}{2} \partial^2 T_n^{kh}.
\]

Adding Gaussian noise to these coefficients for privacy modifies the objective function by

\[
\tilde{a}_k = a_k + \mathcal{N}(0, (\Delta a_k)^2 \sigma^2), \quad \tilde{b}_k = b_k + \mathcal{N}(0, (\Delta b_k)^2 \sigma^2 I), \quad \tilde{C}_k = C_k + \mathcal{N}(0, (\Delta C_k)^2 \sigma^2 I)
\]

where \( \tilde{a}_k \) and \( \tilde{b}_k \) are the noisy coefficients, and the amount of additive Gaussian noise depends on the sensitivity \( (\Delta a_k, \Delta b_k, \Delta C_k) \) of each term. When using a purely gradient-based optimization routine (e.g. Adam, unlike Conjugate Gradient), we don’t have to perturb \( a_k \) and in the case of first order approximation this leaves only \( b_k \). This method is not limited to MSE objectives and in the classification task we use a binary cross-entropy objective analogously in the output layer.

Note that on the first \( W \) step, unperturbed 1st and 2nd-order approximations provide the same gradient. In this case, if we use vanilla SGD to optimize this first order approximation, this boils down to a variant of DP-SGD, which optimizes each layer objective function separately. Empirically, however, we found that we get better results than DP-SGD, thanks to (a) the flexibility in choosing a better optimizer in our case and (b) the tighter sensitivity per layer than the pre-defined clipping norm for the entire weights in SGD, as illustrated in Sec. 3.

Analytic Sensitivities of the coefficients are given in the appendix. Depending on the architecture of a neural network and dataset at hand, these analytic sensitivity bounds can often be loose, in which case we propose to take a more direct approach and bound the losses directly by clipping the norms of \( b_k, C_k \) to some fixed values \( T_{b_k}, T_{C_k} \). Our method for selecting these norms is detailed in Sec. 2.4.

### 2.3 Calculation of cumulative privacy loss

Using the moments accountant and the theorem for subsampled Gaussian mechanism given in [6] for composition requires caution, since the log moments of privacy loss are linearly growing, only if we draw fresh noise per

\[
\mathbb{E}(w) = \left[ \mathbb{E}_1(w_1), \ldots, \mathbb{E}_K(w_K) \right] \text{.}
\]

Then, we scale down each objective function by its own sensitivity times \( \sqrt{K} \), so that the concatenated vector’s sensitivity is 1. Then, we add the standard Gaussian noise with standard deviation \( \sigma \) to the vectors and scale up each perturbed quantities by their own sensitivity times \( \sqrt{K} \). Details are given in appendix H. The DP-MAC algorithm is summarized in Algorithm 1.

#### Algorithm 1 DP-MAC algorithm

Require: Dataset \( \mathcal{D} \), total number of iterations \( T \), privacy parameter \( \sigma^2 \), sampling rate \( q \)

Ensure: \((\varepsilon, \delta)\)-DP weights \( \{W_k\}_{k=1}^{K+1} \)

for number of iterations \( \leq T \) do

1. Optimize eq. 2 for \( Z \)
2. Optimize eq. 5 (noised-up objective) for \( W \)
end for

Calculate the total privacy loss \((\varepsilon, \delta)\) using moments accountant

### 2.4 Layer-wise bounds for tighter sensitivity

In deep models, the magnitude of layer losses often differs significantly. As a result, it can be beneficial to select separate clipping thresholds \( T_{b_k} \) and \( T_{C_k} \) per layer. This can be achieved in a differentially private manner using pre-training and a histogram release, as we explain in detail for \( T_{b_k} \) in this section (and the same holds for \( T_{C_k} \)). While [15] uses a dynamically computed bound per batch, we found that doing so incurs a large privacy loss and similar performance can be achieved with static bounds computed prior to training.

**Learning \( T_{b_k} \) per layer** To determine individual \( T_{b_k} \), we start by using an initial threshold \( T_{b_k}^{\text{max}} \) for all layers and training the model for a short time (e.g. 1 epoch) using DP-MAC. This pre-trained model is then used to record the norms of feature representations for each layer and each sample in the dataset. For each layer, these values are aggregated into a histogram over the interval \([0, T_{b_k}^{\text{max}}]\) which is released in a differentially private manner using the Gaussian mechanism [16] to perturb each bin. Each \( T_{b_k} \) is chosen as the upper border of the

\[1\text{Note that due to the additivity of noise, we can rewrite the perturbed per-layer objective as a sum of original objective plus a single noise term that is a sum of all the noise terms for the coefficients.}\]
Privacy analysis for DP-MAC with learning $T_{bk}$ The privacy costs of each part (pre-training, histogram release and actual training) are computed individually and then summed using basic additive composition. As both training parts follow the same analysis, only the histogram release is left to be explained. Each histogram contains one count per sample, giving it sensitivity 1, as adding or removing a single sample only changes the total count of a single bin by one. Each bin is therefore perturbed using the Gaussian mechanism with a chosen privacy parameter $\sigma_{hist}$. Across layers, the privacy loss is aggregated using the moments accountant with the log moment of the Gaussian mechanism defined as $\alpha_G(\lambda) = (\lambda^2 + \lambda)/4\sigma^2$ [15]. As the total count of each histogram equals the size of the dataset, $\sigma_{hist}$ can be chosen large enough that the privacy cost of the histogram release is negligible compared to the MAC-training without significantly affecting the results. A summary of the algorithm can be found in Appendix C.

3 Experiments

Autoencoder We highlight the advantages of DP-MAC, when training deeper models, in a reconstruction task with a fully connected autoencoder with 6 layers, as used in the original MAC paper [12] with the difference of using softplus activations in all layers, and not storing any $z$ values. For this, we use the USPS dataset is a collection of 16x16 pixel grayscale handwritten digits, of with we use 5000 samples for training and 1000 for testing. We provide results for $\varepsilon$ values of 1, 2, 4, 8 with $\delta = 1e-5$. For comparison, we train the same model using DP-SGD. As suggested in [6], we clipped the gradients using the mean gradient norms, although obtaining the clipping norm is not taken into account in the privacy analysis. For stability of training, we additionally introduce a maximum norm bound $T_g$.

In Fig 1, we observe that DP-MAC significantly outperforms DP-SGD on this task. We suspect that this is in part owed to the difference in norm clipping between the two methods. While DP-SGD normalizes the per-sample gradients across all layers as a whole, DP-MAC normalizes loss (and thus the resulting gradients) per layer, preventing layers with larger gradients from drowning out the rest. We also observe that DP-MAC using the Adam optimizer converges significantly faster than DP-SGD using the vanilla SGD optimizer. We show how the reconstructions of USPS data look in different private settings in Appendix C.

Classifier Due to the page limit, in Appendix B we show the performance of our method compared to other existing methods on a classification task, where our method achieves a comparable test accuracy under the same privacy constraint within a relatively small number of training epochs.

4 Conclusion

We present a novel differentially private deep learning paradigm, DP-MAC, which allows us to compute the sensitivity of the approximate objective functions analytically. For obtaining tighter sensitivities, we propose to use the DP-histogram mechanism to learn the sensitivity privately from the data. Since DP-MAC perturbs the objective function itself, we can decrease the cumulative privacy loss significantly by choosing to use a more efficient optimizer than vanilla SGD.

Appendix A: Differential Privacy Background

Here we provide background information on the definition of algorithmic privacy and a composition method that we will use in our algorithm, as well as the general formulation of the MAC algorithm.

Differential privacy

Differential privacy (DP) is a formal definition of the privacy properties of data analysis algorithms [5]. Given an algorithm $\mathcal{M}$ and neighbouring datasets $D, D'$ differing by a single entry. Here, we focus on the inclusion-exclusion\(^1\) case, i.e., the dataset $D'$ is obtained by excluding one datapoint from the dataset $D$. The privacy loss random variable of an outcome $o$ is $L^{(o)} = \log \frac{Pr(\mathcal{M}(D)=o)}{Pr(\mathcal{M}(D')=o)}$. The mechanism $\mathcal{M}$ is called $\varepsilon$-DP if and only if $|L^{(o)}| \leq \varepsilon, \forall o$. A weaker version of the above is $(\varepsilon, \delta)$-DP, if and only if $|L^{(o)}| \leq \varepsilon,$ with probability at least $1 - \delta$. What the definition states is that a single individual's participation in the data do not change the output probabilities by much, which limits the amount of information that the algorithm reveals about any one individual.

The most common form of designing differentially private algorithms is by adding noise to a quantity of interest, e.g., a deterministic function $h : D \to \mathbb{R}^p$ computed on sensitive data $D$. See [5] and [17] for more forms of designing differentially-private algorithms. For privatizing $h$, one could use the Gaussian mechanism [16] which adds noise to the function, where the noise is calibrated to $h$’s sensitivity, $S_h$, defined by the maximum difference in terms of L2-norm, $||h(D) - h(D')||_2$, $\tilde{h}(D) = h(D) + \mathcal{N}(0, S_h^2 \sigma^2 I_p)$, where $\mathcal{N}(0, S_h^2 \sigma^2 I_p)$ means the Gaussian distribution with mean 0 and covariance $S_h^2 \sigma^2 I_p$. The perturbed function $\tilde{h}(D)$ is $(\varepsilon, \delta)$-DP, where $\sigma \geq \sqrt{2 \log(1.25/\delta)}/\varepsilon$. In this paper, we use the Gaussian mechanism to achieve differentially private network weights. Next, we describe how the cumulative privacy loss is calculated when we use the Gaussian mechanism repeatedly during training.

The moments accountant

In the moments accountant, a cumulative privacy loss is calculated by bounding the moments of $L^{(o)}$, where the $\lambda$-th moment is defined as the log of the moment generating function evaluated at $\lambda$ [6]: $\alpha_M(\lambda; D, D') = \log E_{o\sim \mathcal{M}(D)}[e^{\lambda L^{(o)}}]$. By taking the maximum over the neighbouring datasets, we obtain the worst case $\lambda$-th moment $\alpha_M(\lambda) = \max_{D,D'} \alpha_M(\lambda; D, D')$, where the form of $\alpha_M(\lambda)$ is determined by the mechanism of choice. The moments accountant compute $\alpha_M(\lambda)$ at each step. Due to the compositability theorem which states that the $\lambda$-th moment composes linearly (See the compositability theorem: Theorem 2.1 in [6] when independent noise is added in each step, we can simply sum each upper bound on $\alpha_M$, to obtain an upper bound on the total $\lambda$-th moment after $T$ compositions, $\alpha_M(\lambda) \leq \sum_{j=1}^{T} \alpha_M(\lambda)$. Once the moment bound is computed, we can convert the $\lambda$-th moment to the $(\varepsilon, \delta)$-DP, guarantee by, $\delta = \min_{\lambda} \exp[\alpha_M(\lambda) - \lambda\varepsilon]$, for any $\varepsilon > 0$. See Appendix A in [6] for the proof.

\(^1\)This is for using the moments accountant method when calculating the cumulative privacy loss.

Figure 4: Autoencoder reconstructions (left) of USPS test set samples (right) for average mean squared error rates after training in both non-private and private settings
Appendix D: sensitivity of $a_k$

We are using a few assumptions and facts to derive sensitivities below.

- $||z_{k,n}||_2 \leq T_z$ for a predefined threshold $T_z$ for all $k, n$.
- $||w_{kh}||_2 \leq T_w$ for a predefined threshold $T_w$ for all $k$ and $h$.
- Due to Cauchy-Schwarz inequality: $w_{kh}^T z_{k-1,n} \leq ||w_{kh}||_2 T_z$
- Using a monotonic nonlinearity (e.g., softplus): $f(w_{kh}^T z_{k-1,N}) \leq f(||w_{kh}||_2 T_z)$ and $f'(w_{kh}^T z_{k-1,N}) \leq f'(||w_{kh}||_2 T_z)$
- For softplus, $0 < f'(w_{kh}^T z_{k-1,N}) \leq f'(||w_{kh}||_2 T_z) \leq 1$ and $0 < f''(w_{kh}^T z_{k-1,n}) \leq \frac{1}{4}$
- $||a||_2 \leq ||a||_1 \leq ||a||_2 \sqrt{D}$ for $a \in \mathbb{R}^D$
- Direct application of above: $|\sum_{h=1}^{D_{out}} z_{kh,n}| \leq |\sum_{h=1}^{D_{out}} |z_{kh,n}| = ||z_{k,n}||_1 \leq T_z \sqrt{D_{out}}$

Denote

$$\alpha_{wh} := f(||\tilde{w}_{kh}||_2 T_z)$$
$$\beta_{wh} := f'(||\tilde{w}_{kh}||_2 T_z)$$

which we will further denote as vectors $\alpha_{\tilde{w}}, \beta_{\tilde{w}}$.

Without loss of generality, we further assume that (1): the neighbouring datasets are in the form of $\mathcal{D} = \{\mathcal{D}', (x_N, y_N)\}$; and (2) the last entry maximizes the difference in $a_k$ run on $\mathcal{D}, \mathcal{D}'$, i.e., the average over the first $(N-1)$ entries in $a_k$ cannot exceed the value of the last entry in $a_k$.

$$\Delta a_k = \max_{|\mathcal{D}'|=1} |a_k(\mathcal{D}) - a_k(\mathcal{D}')|,$$

$$= \max_{|\mathcal{D}\backslash\mathcal{D}'|=1} \frac{1}{2} \left| \sum_{h=1}^{D_{out}} \left( \sum_{n=1}^{N} (T_n(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{nkh} \tilde{w}_{kh}) - \frac{1}{N-1} \sum_{n=1}^{N} (T_n(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{nkh} \tilde{w}_{kh}) \right) \right|$$

$$= \max_{|\mathcal{D}\backslash\mathcal{D}'|=1} \frac{1}{N-1} \left| \sum_{h=1}^{D_{out}} \left( \sum_{n=1}^{N-1} (T_n(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{nkh} \tilde{w}_{kh}) + \frac{1}{N} (T_N(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{Nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{Nkh} \tilde{w}_{kh}) \right) \right|$$

$$\leq \max_{|\mathcal{D}\backslash\mathcal{D}'|=1} \frac{1}{2N} \left| \sum_{h=1}^{D_{out}} \left( \sum_{n=1}^{N-1} (T_n(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{nkh} \tilde{w}_{kh}) \right) \right|$$

$$+ \frac{1}{2N} \left| \sum_{h=1}^{D_{out}} (T_N(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{Nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{Nkh} \tilde{w}_{kh}) \right|, \text{ due to Triangle inequality}$$

$$\leq \max_{|\mathcal{D}\backslash\mathcal{D}'|=1} \frac{1}{2N} \left| \sum_{h=1}^{D_{out}} (T_N(\tilde{w}_{kh}) - \tilde{w}_{kh} \partial T_{Nkh} + \frac{1}{2} \tilde{w}_{kh} \partial^2 T_{Nkh} \tilde{w}_{kh}) \right|, \text{ due to assumption (2).}$$
Now the sensitivity can be divided into three terms due to triangle inequality as

\[
\Delta a_k \leq \max_{|D'|=1} \left\{ \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} T_N(\hat{w}_{kh}) + \max_{|D'|=1} \left[ \frac{2}{2N} \sum_{h=1}^{D_{out}^k} \hat{w}_{kh}^\top \partial T_{Nkh} \right] + \max_{|D'|=1} \left[ \frac{2}{2N} \sum_{h=1}^{D_{out}^k} \frac{1}{2} \hat{w}_{kh}^\top \partial^2 T_{Nkh} \hat{w}_{kh} \right] \right\}.
\]

We compute the sensitivity of each of these terms below. The sensitivity of \(a_{k_1}\) is given by

\[
\Delta a_{k_1} = \frac{1}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left| \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} z^2_{kh,N} - 2z_{kh,N} f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) + (f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}))^2 \right|
\]

\[
\leq \frac{1}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left| \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} z^2_{kh,N} \right| + \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} 2z_{kh,N} f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) + \frac{D_{out}^k}{2N} (f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}))^2 \right|
\]

\[
\leq \frac{1}{N} \left( T_z^2 + 2T_z \| \alpha_{\hat{w}_k} \|_2 + \| \beta_{\hat{w}_k} \|_2^2 \right)
\]

The sensitivity of \(a_{k_2}\) is given by

\[
\Delta a_{k_2} = \frac{1}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left| \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} \left( -2z_{kh,N} f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) + 2f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \right) \hat{w}_{kh}^T \mathbf{z}_{k-1,N} \right|
\]

\[
\leq \frac{1}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left| \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} \left( 2z_{kh,N} f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \right) \hat{w}_{kh}^T \mathbf{z}_{k-1,N} \right| + \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} (2f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N})) \hat{w}_{kh}^T \mathbf{z}_{k-1,N} \right|
\]

\[
\leq \frac{1}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left| \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} \left( 2z_{kh,N} f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \right) \hat{w}_{kh} \|_2 \cdot \| \mathbf{z}_{k-1,N} \|_2 \right| + \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} \| 2f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \hat{w}_{kh} \|_2 \cdot \| \mathbf{z}_{k-1,N} \|_2 \right|
\]

\[
\leq \frac{2T_z}{N} \max_{z_{k,N}, \mathbf{z}_{k-1,N}} \left( \frac{1}{2} \sum_{h=1}^{D_{out}^k} z_{kh,N} \cdot \| f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \hat{w}_{kh} \|_2 \right) + \frac{D_{out}^k}{2N} \sum_{h=1}^{D_{out}^k} \| f(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) f'(\hat{w}_{kh}^T \mathbf{z}_{k-1,N}) \hat{w}_{kh} \|_2 \right]
\]

\[
\leq \frac{2T_z}{N} \left( T_z \cdot \left( \sum_{h=1}^{D_{out}^k} \beta_{\hat{w}_{kh}} \| \mathbf{w}_{kh} \|_2^2 \right)^{1/2} + \sum_{h=1}^{D_{out}^k} | \alpha_{\hat{w}_{kh}} \beta_{\hat{w}_{kh}} \cdot \| \hat{w}_{kh} \|_2 \right),
\]

The sensitivity of \(a_{k_3}\) is given by
\[
\Delta a_{k3} = \frac{1}{N} \max_{z_{k,N} \cdot z_{k-1,N}} \left| \sum_{h=1}^{D_{out}^k} \left( -z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) + \left( f'(\hat{w}_{kh}^T z_{k-1,N}) f''(\hat{w}_{kh}^T z_{k-1,N}) \right) \right) \right| \left| \hat{w}_{kh}^T z_{k-1,N} \right| \\
\leq \frac{1}{N} \max_{z_{k,N} \cdot z_{k-1,N}} \left| \sum_{h=1}^{D_{out}^k} \left( z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) \right) \right| \left| \hat{w}_{kh}^T z_{k-1,N} \right| + \left| \sum_{h=1}^{D_{out}^k} \left( f'(\hat{w}_{kh}^T z_{k-1,N}) \right) \right| \left| \hat{w}_{kh}^T z_{k-1,N} \right|^2 \\
\leq \frac{1}{N} \max_{z_{k,N} \cdot z_{k-1,N}} \left| \sum_{h=1}^{D_{out}^k} \left( z_{kh,N} \cdot f''(\hat{w}_{kh}^T z_{k-1,N}) \cdot ||\hat{w}_{kh}||^2 \cdot ||z_{k-1,N}||^2 \right) + \left| \sum_{h=1}^{D_{out}^k} \left( f'(\hat{w}_{kh}^T z_{k-1,N}) \right) \cdot ||\hat{w}_{kh}||^2 \cdot ||z_{k-1,N}||^2 \right| \\
\leq \frac{T^2}{N} \max_{z_{k,N}} \left( \sum_{h=1}^{D_{out}^k} \frac{1}{4} \cdot z_{kh,N} \cdot ||\hat{w}_{kh}||^2 \right) \sum_{h=1}^{D_{out}^k} (\beta_{\hat{w}_{kh}})^2 \cdot ||\hat{w}_{kh}||^2 + \sum_{h=1}^{D_{out}^k} \frac{1}{4} \alpha_{\hat{w}_{kh}} \cdot ||\hat{w}_{kh}||^2 \\
\leq \frac{T^2}{4N} \left( \sum_{h=1}^{D_{out}^k} (||\hat{w}_{kh}||^2)^2 \right)^{1/2} + \sum_{h=1}^{D_{out}^k} \left( (\beta_{\hat{w}_{kh}})^2 + \alpha_{\hat{w}_{kh}} \right) \cdot ||\hat{w}_{kh}||^2 ) \\
\leq \frac{1}{N} \left( \Delta b_{k1} + \Delta b_{k2} \right)^2.
\]

**Appendix E: sensitivity of $b_k$**

\[
\Delta b_k = \max_{|D \setminus D'|=1} \left| b_k(D) - b_k(D') \right| \in F = \max_{|D \setminus D'|=1} \left( \sum_{h=1}^{D_{out}^k} ||b_{kh}(D) - b_{kh}(D')||^2 \right)^{1/2},
\]

\[
\leq \max_{z_{k,N} \cdot z_{k-1,N} \cdot z_{k,N} \cdot z_{k-1,N}} \frac{1}{N} \left( \sum_{h=1}^{D_{out}^k} \left| (\partial T_N(\hat{w}_{kh}) - \hat{w}_{kh}) \hat{w}_{kh} \right| - (\partial T_N'(\hat{w}_{kh}) - \hat{w}_{kh}) \right)^{1/2}
\]

\[
\leq \frac{1}{N} \left( \Delta b_{k1} + \Delta b_{k2} \right)^2,
\]
where

\[ \Delta b_{k1} = \max_{z_{k,N}, z_{k-1,N}, z'_{k,N}, z'_{k-1,N}} \sum_{h=1}^{D_{out}^k} || \partial T_N(\hat{w}_{kh}) - \partial T'_N(\hat{w}_{kh}) ||_2^2 \]  

(6)

\[ \Delta b_{k2} = \max_{z_{k,N}, z_{k-1,N}, z'_{k,N}, z'_{k-1,N}} \sum_{h=1}^{D_{out}^k} || \partial T_N(\hat{w}_{kh}) \hat{w}_{kh} - \partial T'_N(\hat{w}_{kh}) \hat{w}_{kh} ||_2^2, \]  

(7)

\[ \Delta b_{k1} = \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} || ( -2z_{kh,N} f'(\hat{w}_{kh}^T z_{k-1,N}) + 2 f(\hat{w}_{kh}^T z_{k-1,N}) f'(\hat{w}_{kh}^T z_{k-1,N}) ) \hat{w}_{kh} ||_2^2 \]  

\[ \leq 2 \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} |z_{kh,N} f'(\hat{w}_{kh}^T z_{k-1,N})|^2 ||z_{k-1,N}||_2^2 + \sum_{h=1}^{D_{out}^k} |f(\hat{w}_{kh}^T z_{k-1,N}) f'(\hat{w}_{kh}^T z_{k-1,N})|^2 ||z_{k-1,N}||_2^2 \]  

\[ \leq 2T^2 z \max_{z_{k,N}} \sum_{h=1}^{D_{out}^k} |z_{kh,N}|^2 + \sum_{h=1}^{D_{out}^k} |\alpha \hat{w}_{k,h} \beta \hat{w}_{kh} |^2, \quad \text{since } \beta \hat{w}_{k,h} \leq 1 \]  

\[ \leq 2T^2 z (T^2 + || \alpha \hat{w}_{k} \odot \beta \hat{w}_{k} ||_2^2) \]  

(8)

\[ \Delta b_{k2} = \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} || \left( -2z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) + 2 f'(\hat{w}_{kh}^T z_{k-1,N}) f''(\hat{w}_{kh}^T z_{k-1,N}) \right) \hat{w}_{kh} ||_2^2 \]  

\[ \leq 2 \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} |z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) z_{k-1,N} z_{k-1,N}^T \hat{w}_{kh} ||_2^2 + || f'(\hat{w}_{kh}^T z_{k-1,N}) ||_2^2 ||z_{k-1,N} z_{k-1,N}^T \hat{w}_{kh} ||_2^2 \]  

\[ \leq 2 \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} |1/4 \cdot z_{kh,N} z_{k-1,N} z_{k-1,N}^T \hat{w}_{kh} ||_2^2 \]  

\[ + || \left( f'(\hat{w}_{kh}^T z_{k-1,N}) \right) ||_2^2 + 1/4 \cdot f(\hat{w}_{kh}^T z_{k-1,N}) ||z_{k-1,N} z_{k-1,N}^T \hat{w}_{kh} ||_2^2 \]  

\[ \leq 2 \max_{z_{k,N}, z_{k-1,N}} \sum_{h=1}^{D_{out}^k} |1/4 \cdot z_{kh,N} ||_2^2 \cdot T^2_z \cdot T^2_z || \hat{w}_{kh} ||_2^2 \]  

\[ + || \left( f'(\hat{w}_{kh}^T z_{k-1,N}) \right) ||_2^2 + 1/4 \cdot f(\hat{w}_{kh}^T z_{k-1,N}) || \hat{w}_{kh} ||_2^2 \cdot T^2_z \cdot T^2_z \]  

\[ \leq \frac{T^4}{8} \left( T^2_z || \hat{w}_k ||_2^2 + \sum_{h=1}^{D_{out}^k} || 4 \beta \hat{w}_{k,h} + \alpha \hat{w}_{k,h} | \hat{w}_{kh} ||_2^2 \right) \]  

(17)
Appendix F: sensitivity of $C_k$

The sensitivity of $\Delta C_k$ is given by

$$\Delta C_k = \max_{|D \setminus D'| = 1} \left| C_k(D) - C_k(D') \right|_F,$$

$$= \max_{|D \setminus D'| = 1} \left( \sum_{h=1}^{D_{out}} \left| \left| C_{kh}(D) - C_{kh}(D') \right|_F^2 \right)^{1/2} \right)^{1/2}$$

(18)

where

$$C_{kh}(D) = \frac{1}{2N} \sum_{n=1}^{N} T_{nkh},$$

$$= \frac{1}{2N} \sum_{n=1}^{N} \left[ -2z_{kh,n} f''(\hat{w}_{kh}^T z_{k-1,n}) + 2f'(\hat{w}_{kh}^T z_{k-1,n}) f''(\hat{w}_{kh}^T z_{k-1,n}) \right] z_{k-1,n} z_{k-1,n}^T.$$

Due to the triangle inequality,

$$\Delta C_k \leq \frac{1}{2N} \max_{z_{k,N},z_{k-1,N}} \left( \sum_{h=1}^{D_{out}} \left| \Delta C_{kh} \right|_F^2 \right)^{1/2}$$

$$= \frac{1}{2N} \max_{z_{k,N},z_{k-1,N}} \left( \sum_{h=1}^{D_{out}} \left| \left| -2z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) + 2f'(\hat{w}_{kh}^T z_{k-1,N}) f''(\hat{w}_{kh}^T z_{k-1,N}) \right|_F^2 \right) \right)^{1/2}$$

$$\leq \frac{T^2}{N} \max_{z_{k,N},z_{k-1,N}} \left( \sum_{h=1}^{D_{out}} \left| \left| z_{kh,N} f''(\hat{w}_{kh}^T z_{k-1,N}) \right|_F^2 + \left| f'(\hat{w}_{kh}^T z_{k-1,N}) \right|_F^2 + \left| f''(\hat{w}_{kh}^T z_{k-1,N}) \right|_F^2 \right) \right)^{1/2}$$

$$\leq \frac{T^2}{4N} \left( T^2 + \left| \left| \beta_{\hat{w}_k} \right|_F^2 + \alpha_{\hat{w}_k} \right|_F^2 \right)^{1/2}$$
Appendix G: sensitivity of coefficients in the output layer objective function

\[ \Delta a_o \leq \frac{1}{2N} \max_{\mathbf{z}_{K,N}} \sum_{h=1}^{D^o_{out}} \left| f(f'(\hat{w}^T_{K+1|h}z_{K,N}) - w^T_{K+1|h}f'(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N} + 1/2w^T_{K+1|h}f''(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N}z_{K,N}^Tw_{K+1|h} \right| \]

\[ \leq \frac{1}{2N} \max_{\mathbf{z}_{K,N}} \sum_{h=1}^{D^o_{out}} \left| f(f'(\hat{w}^T_{K+1|h}z_{K,N}) \right| + \sum_{h=1}^{D^o_{out}} \left| w^T_{K+1|h}f'(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N} \right| + \sum_{h=1}^{D^o_{out}} \left| 1/2w^T_{K+1|h}f''(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N}z_{K,N}^Tw_{K+1|h} \right| \]

\[ \leq \frac{1}{2N} \left( ||a_{w_{K+1}}||_1 + Tz \sum_{h=1}^{D^o_{out}} ||w_{K+1|h} \cdot \beta_{w_{K+1|h}}||_2 + \frac{T^2}{8} ||w_{K+1}||_F^2 \right) \]

\[ \Delta b_o \leq \frac{1}{2N} \max_{\mathbf{y},\mathbf{z}_{K,N}} \left( \sum_{h=1}^{D^o_{out}} \left| yh_{z_{K,N}} + f'(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N} - f''(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N}z_{K,N}^Tw_{K+1|h} \right| \right)^{1/2} \]

\[ \leq \frac{1}{2N} \max_{\mathbf{y},\mathbf{z}_{K,N}} \left( \sum_{h=1}^{D^o_{out}} \left| yh_{z_{K,N}} \right|_2^2 + \sum_{h=1}^{D^o_{out}} \left| f'(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N} \right|_2^2 + \sum_{h=1}^{D^o_{out}} \left| f''(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N}z_{K,N}^Tw_{K+1|h} \right|_2^2 \right)^{1/2} \]

\[ \leq \frac{1}{2N} \left( D^o_{out} T^2_z + T^2 \cdot ||\beta_{w_{K+1}}||_2^2 + 1/16 \cdot T^4 \cdot ||W||^2_F \right)^{1/2} \]

\[ \Delta C_o \leq \frac{1}{2N} \max_{\mathbf{z}_{K,N}} \left( \sum_{h=1}^{D^o_{out}} \left| 1/2f''(\hat{w}^T_{K+1|h}z_{K,N})z_{K,N}z_{K,N}^Tw_{K+1|h} \right|_F^2 \right)^{1/2} \]

\[ \leq \frac{1}{2N} \max_{\mathbf{z}_{K,N}} \left( \sum_{h=1}^{D^o_{out}} \left| 1/8z_{K,N}z_{K,N}^Tw_{K+1|h} \right|_F^2 \right)^{1/2} \]

\[ \leq \frac{1}{16N} \sqrt{D^o_{out}} T^2_z \]

Appendix H: Computing a cumulative privacy loss

Preliminary

We first address how the level of perturbation in the coefficients affects the level of privacy in the resulting estimate. Suppose we have an objective function that’s quadratic in \( w \), i.e.,

\[ E(w) = a + bw + cw^2, \quad (19) \]
where only the coefficients $a, b, c$ contain the information on the data (not anything else in the objective function is relevant to data). We perturb the coefficients to ensure the coefficients are collectively $(\epsilon, \delta)$-differentially private.

\[
\tilde{a} = a + n_a, \quad \text{where } n_a \sim \mathcal{N}(0, \Delta_a^2 \sigma^2),
\]

\[
\tilde{b} = b + n_b, \quad \text{where } n_b \sim \mathcal{N}(0, \Delta_b^2 \sigma^2),
\]

\[
\tilde{c} = c + n_c, \quad \text{where } n_c \sim \mathcal{N}(0, \Delta_c^2 \sigma^2),
\]

where $\Delta_a, \Delta_b, \Delta_c$ are the sensitivities of each term, and $\sigma$ is a function of $\epsilon$ and $\delta$. Here “collectively” means composing the perturbed $\tilde{a}, \tilde{b}, \tilde{c}$ results in $(\epsilon, \delta)$-DP. For instance, if one uses the linear composition method (privacy degrades with the number of compositions), and perturbs each of these with $\epsilon_a$, $\epsilon_b$, and $\epsilon_c$, then the total privacy loss should match the sum of these losses, i.e., $\epsilon = \epsilon_a + \epsilon_b + \epsilon_c$. In this case, if one allocates the same privacy budget to perturb each of these coefficients, then $\epsilon_a = \epsilon_b = \epsilon_c = \epsilon/3$. The same holds for $\delta$.

However, if one uses more advanced composition methods and allocates the same privacy budget for each perturbation, per-perturbation budget becomes some function (denoted by $g$) of total privacy budget $\epsilon$, i.e., $\epsilon_a = \epsilon_b = \epsilon_c = g(\epsilon)$, where $g(\epsilon) \geq \epsilon/3$. So, per-perturbation for $a, b, c$ has a higher privacy budget to spend, resulting in adding less amount of noise.

Whatever composition methods one uses to allocate the privacy budget in each perturbation of those coefficients, since the objective function is a simple quadratic form in $w$, the resulting estimate of $w$ is some function of those perturbed coefficients, i.e., $\hat{w} = h(\hat{a}, \hat{b}, \hat{c})$. Since the data are summarized in the coefficients and the coefficients are $(\epsilon, \delta)$-differentially private, the function of these coefficients is also $(\epsilon, \delta)$-differentially private.

One could write the perturbed objective as

\[
\tilde{E}(w) = \tilde{a} + \tilde{b}w + \tilde{c}w^2,
\]

\[
= (a + bw + cw^2) + (n_a + n_bw + n_cw^2),
\]

\[
= E(w) + n(w).
\]

Note that we write down the noise term as $n(w)$ to emphasize that when we optimize this objective function, the noise term also contributes to the gradient with respect to $w$ (not just the term $E(w)$).

If we denote some standard normal noise $\alpha \sim \mathcal{N}(0, 1)$, we can rewrite the noise term as

\[
n(w) = (\Delta_a + \Delta_bw + \Delta_cw^2)\sigma\alpha,
\]

which is equivalent to

\[
n(w) \sim \mathcal{N}(0, (\Delta_a + \Delta_bw + \Delta_cw^2)^2\sigma^2),
\]

\[
\sim \mathcal{N}(0, \Delta_{E(w)}^2\sigma^2)
\]

where we denote $\Delta_{E(w)} = \Delta_a + \Delta_bw + \Delta_cw^2$.

**Extending the preliminary to DP-MAC**

In the framework of DP-MAC, given a mini-batch of data $D_q$ with a sampling rate $q$, the DP-mechanism we introduce first computes layer-wise objective functions ($k$ layer-wise objective functions for a model with $k$ layers, including the output layer), then noise up the coefficients of each of the layer-wise objective functions using Gaussian noise, and then
outputs the vector of perturbed objective function, given by:

$$M(D_q) = \begin{bmatrix} E_1(w_1) \\ \vdots \\ E_K(w_K) \end{bmatrix} + \begin{bmatrix} n_1^*(w_1) \\ \vdots \\ n_K^*(w_K) \end{bmatrix}. \quad (29)$$

We denote the noise terms by $n_k^*(w_k)$ and the sensitivities of each objective by $\Delta E_1(w_1), \ldots, \Delta E_K(w_K)$, where each of these is a function of $\Delta a_k, \Delta b_k, \Delta c_k$, and $w_k$.

Here the question is, if we decide to use an advanced composition method such as moments accountant, how the log-moment of the privacy loss random variable composes in this case. To directly use the composition theorem of Abadi et al, we need to draw a fresh noise whenever we have a new subsampled data. This means, there should be an instance of Gaussian mechanism that affects the these noise terms simultaneously.

To achieve this, we rewrite the vector of perturbed objectives as $\tilde{E}(w)$ as below. Then, we scale down each objective function by its own sensitivity times $\sqrt{K}$, so that the concatenated vector’s sensitivity becomes just 1. Then, add the standard normal noise to the vectors with scaled standard deviation, $\sigma$. Then, scale up each perturbed quantities by its own sensitivity times $\sqrt{K}$.

$$\tilde{E}(w) = \begin{bmatrix} \tilde{E}_1(w_1) \\ \vdots \\ \tilde{E}_K(w_K) \end{bmatrix}, \quad (30)$$

$$= \begin{bmatrix} E_1(w_1) \\ \vdots \\ E_K(w_K) \end{bmatrix} + \begin{bmatrix} n_1^*(w_1) \\ \vdots \\ n_K^*(w_K) \end{bmatrix}, \quad (31)$$

$$= \sqrt{K} \Delta E_1(w_1) \cdot \left\{ \frac{E_1(w_1)}{\sqrt{K} \Delta E_1(w_1)} + \sigma N(0, 1) \right\},$$

$$\sqrt{K} \Delta E_K(w_K) \cdot \left\{ \frac{E_K(w_K)}{\sqrt{K} \Delta E_K(w_K)} + \sigma N(0, 1) \right\}, \quad (32)$$

$$\sqrt{K} \Delta E_K(w_K) \cdot \left( \begin{bmatrix} \frac{E_1(w_1)}{\sqrt{K} \Delta E_1(w_1)} \\ \vdots \\ \frac{E_K(w_K)}{\sqrt{K} \Delta E_K(w_K)} \end{bmatrix} + N(0, \sigma^2 I) \right) \quad (33)$$

Since we’re adding independent Gaussian noise under each subsampled data, the privacy loss after $T$ steps, is simply following the compositibility theorem in the Abadi et al paper.

So compared to the sensitivity for $n(w)$ in the first section, the new noise $n^*(w)$ has a higher sensitivity due to the factor $\sqrt{K}$.

**Moments Calculations**

In this case, with a subsampling with rate $q$, we re-do the calculations in Abadi et al. First, let:

$$\mu_0 = N(0_K, \sigma^2 I), \mu_1 = N(1_K, \sigma^2 I) \quad (34)$$
and let $\mu$ as a mixture of the two Gaussians,

$$\mu = (1 - q)N(0_K, \sigma^2 I) + qN(1_K, \sigma^2 I).$$  (35)

Here $0_K$ is the $K$-dimensional 0 vector, and $1_K$ is the $K$-dimensional all ones vector. Here $\alpha_M(\lambda)$ should be log max($E_1, E_2$) where

$$E_1 = \mathbb{E}_{z \sim \mu}[(\mu(z)/\mu_0(z))^\lambda], E_2 = \mathbb{E}_{z \sim \mu_0}[(\mu_0(z)/\mu(z))^\lambda]$$

Then, we can compose further mechanisms using this particular $\alpha_M(\lambda)$, which follows the same analysis as in Abadi et al.
